What is the smallest positive integer that has exactly k divisors, for $1 \le k \le 6$?

Prove that $gcd(m, n) \cdot lcm(m, n) = m \cdot n$, and use this identity to express lcm(m, n) in terms of $lcm(n \mod m, m)$, when $n \mod m \neq 0$. Hint: Use (4.12), (4.14), and (4.15).

Proof.

$$\gcd(m,n) \cdot \operatorname{lcm}(m,n) = p_1^{\min(m_1,n_1)} p_2^{\min(m_2,n_2)} \cdots p_k^{\min(m_k,n_k)}.$$

$$= p_1^{\max(m_1,n_1)} p_2^{\max(m_2,n_2)} \cdots p_k^{\max(m_k,n_k)}$$

$$= p_1^{\min(m_1,n_1) + \max(m_1,n_1)} p_2^{\min(m_2,n_2) + \max(m_2,n_2)} \cdots p_k^{\min(m_k,n_k) + \max(m_k,n_k)}$$

$$= p_1^{m_1+n_1} p_2^{m_2+n_2} \cdots p_k^{m_k+n_k}$$

$$= m \cdot n$$
(By (4.14))

$$\operatorname{lcm}(m, n) = \frac{m \cdot n}{\gcd(m, n)}$$

$$= \frac{m \cdot n}{\gcd(n \mod m, m)}$$

$$= \frac{m \cdot n}{\frac{m(n \mod m)}{\operatorname{lcm}(n \mod m, m)}}$$

$$= \frac{m \cdot n}{n \mod m} \cdot \operatorname{lcm}(n \mod m, m) \qquad (n \mod m \neq 0)$$

3 Let $\pi(x)$ be the number of primes not exceeding x. Prove or disprove: $\pi(x) - \pi(x-1) = [x \text{ is prime}].$

Proof. It only holds for x is an integer. x could be a real number. In fact,

$$\pi(x) - \pi(x-1) = [|x| \text{ is prime}]$$

You can only count primes up to $\lfloor x \rfloor$. And if $\lfloor x \rfloor$ is a prime, x-1 will ignore this prime, thus the gap 1. Otherwise, no prime is ignored.

What would happen if the Stern-Brocot construction started with the five fractions $(\frac{0}{1}, \frac{1}{0}, \frac{0}{-1}, \frac{-1}{0}, \frac{0}{1})$ instead of with $(\frac{0}{1}, \frac{1}{0})$?

Solution. All fractions m/n with m|n are constructed.

 $\left(\frac{0}{-1}, \frac{-1}{0}\right)$ will give the negative part fractions. Initial Stage always give:

$$1 \times 1 - 0 \times 0 = 1$$
$$0 \times 0 - 1 \times (-1) = 1$$
$$(-1) \times (-1) - 0 \times 0 = 1$$
$$0 \times 0 - (-1) \times 1 = 1$$

which satisfies the requirement of

$$m'n - mn' = 1$$

and the chain reaction will continue.

5 Find simple formulas for L^k and R^k , when L and R are the 2×2 matrices of (4.33).

Solution.

$$L^k = \begin{pmatrix} 1 & k \\ 0 & 1 \end{pmatrix} \quad R^k = \begin{pmatrix} 1 & 0 \\ k & 1 \end{pmatrix}$$

Prove by mathematical induction.

Basic steps.

$$L = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \quad R = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}$$

Induction. Assumming that

$$L^{k-1} = \begin{pmatrix} 1 & k-1 \\ 0 & 1 \end{pmatrix} \quad R^{k-1} = \begin{pmatrix} 1 & 0 \\ k-1 & 1 \end{pmatrix}$$

Then,

$$L^{k} = L^{k-1}L = \begin{pmatrix} 1 & k-1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & k \\ 0 & 1 \end{pmatrix}$$
$$R^{k} = R^{k-1}R = \begin{pmatrix} 1 & 0 \\ k-1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ k & 1 \end{pmatrix}$$

As a result, it holds for all $n \in \mathbb{N}_+$.

6 What does ' $a \equiv b \pmod{0}$ ' mean?

Solution. Based on (4.36):

$$a \equiv b \pmod{0} \Leftrightarrow a - b$$
 is a multiple of 0

Thus,

$$a = b$$

7 Ten people numbered 1 to 10 are lined up in a circle as in the Josephus problem, and every mth person is executed. (The value of m may be much larger than 10.) Prove that the first three people to go cannot be 10, k, and k + 1 (in this order), for any k.

Proof. Prove by contradiction. If the first three people to go is 10, k, and k + 1.

1 2 3 4 5 6 7 8 9 N

1 2 3 **X** 5 6 7 8 9 **M**

 $1 \quad 2 \quad 3 \quad \mathbf{X} \quad \mathbf{X} \quad 6 \quad 7 \quad 8 \quad 9 \quad \mathbf{M}$

The first step implies that

$$m \mod 10 = 0$$

The second step implies that

$$m \bmod 9 = k$$

The third step implies that

$$m \mod 8 = 1$$

A contradiction comes to m can not be both even and odd from the first step and the third step.

Basics

14 Prove or disprove:

a.
$$gcd(km, kn) = kgcd(m, n)$$

Proof. When k is a positive integer, the statement is true. Let

$$m = p_1^{\alpha_1} \cdots p_k^{\alpha_k}$$
$$n = p_1^{\beta_1} \cdots p_k^{\beta_k}$$
$$\gcd(m, n) = p_1^{\gamma_1} \cdots p_k^{\gamma_k}$$

where $\gamma_i = \min(\alpha_i, \beta_i)$. If

$$k = p_1^{\theta_1} \cdots p_k^{\theta_k}$$

Then,

$$\gcd(km, kn) = p_1^{\min(\alpha_1 + \theta_1, \beta_1 + \theta_1)} \cdots p_k^{\min(\alpha_k + \theta_k, \beta_k + \theta_k)}$$
$$= p_1^{\min(\alpha_1, \beta_1)} \cdots p_k^{\min(\alpha_k, \beta_k)} p_1^{\theta_1} \cdots p_k^{\theta_k}$$
$$= k \gcd(m, n)$$

b. lcm(km, kn) = klcm(m, n)

Proof. When k is a positive integer, the statement is true. Let

$$m = p_1^{\alpha_1} \cdots p_k^{\alpha_k}$$

$$n = p_1^{\beta_1} \cdots p_k^{\beta_k}$$

$$\operatorname{lcm}(m, n) = p_1^{\gamma_1} \cdots p_k^{\gamma_k}$$

where $\gamma_i = \max(\alpha_i, \beta_i)$. If

$$k = p_1^{\theta_1} \cdots p_k^{\theta_k}$$

Then,

$$\operatorname{lcm}(km, kn) = p_1^{\max(\alpha_1 + \theta_1, \beta_1 + \theta_1)} \cdots p_k^{\max(\alpha_k + \theta_k, \beta_k + \theta_k)}$$
$$= p_1^{\max(\alpha_1, \beta_1)} \cdots p_k^{\max(\alpha_k, \beta_k)} p_1^{\theta_1} \cdots p_k^{\theta_k}$$
$$= k \operatorname{lcm}(m, n)$$

15 Does every prime occur as a factor of some Euclid number e_n ?

Solution. No. For example,

$$e_1 \mod 5 = 2$$

$$e_2 \mod 5 = 3$$

$$e_3 \mod 5 = 2$$

$$e_4 \mod 5 = 3$$

. . .

In fact, because $e_n \neq 5$, if $e_n \mod 5 = 0$, then e_n is not a prime, which contradicts the property of e_n as a prime.
